RNA-Seq (RNA sequencing), also called whole transcriptome shotgun sequencing (WTSS), uses next-generation sequencing (NGS) to reveal the presence and quantity of RNA in a biological sample at a given moment.. RNA-Seq is used to analyze the continuously changing cellular transcriptome. Specifically, RNA-Seq facilitates the ability to look at alternative gene spliced transcripts, post ...

RNA-Seq - Wikipedia

RNA-Seq is a technique that allows transcriptome studies (see also Transcriptomics technologies) based on next-generation sequencing technologies. This technique is largely dependent on bioinformatics tools developed to support the different steps of the process. Here are listed some of the principal tools commonly employed and links to some important web resources.

The identification of antigen-specific T cell receptors (TCRs) is a complicated process, which is technically challenging and not suitable for clinical applications. To simplify this process, Lu and colleagues developed an efficient single-cell approach, which can significantly reduce the labor and time for the TCR isolation.

Capturing single cells along with sets of uniquely barcoded primer beads together in tiny droplets enables large-scale, highly parallel single-cell transcriptomics. Applying this analysis to cells in mouse retinal tissue revealed transcriptionally distinct cell populations along with molecular markers of each type.

There are numerous ways to describe and present the variation that is inherent to most data sets. Range (defined as the largest value minus the smallest) is one common measure and has the advantage of being simple and intuitive. Range, however, can be misleading because of the presence of outliers, and it tends to be larger for larger sample sizes even without unusual data values.
